Call Center Performance

Where calls are being lost, which agents resolve the most, and what actually moves customer satisfaction, built as an interactive Tableau dashboard.

Tools Tableau. Calculated fields, parameters, dashboard design

Data 5,000 call records, 8 agents, Q1 2021

Live dashboard view on Tableau Public

The questions

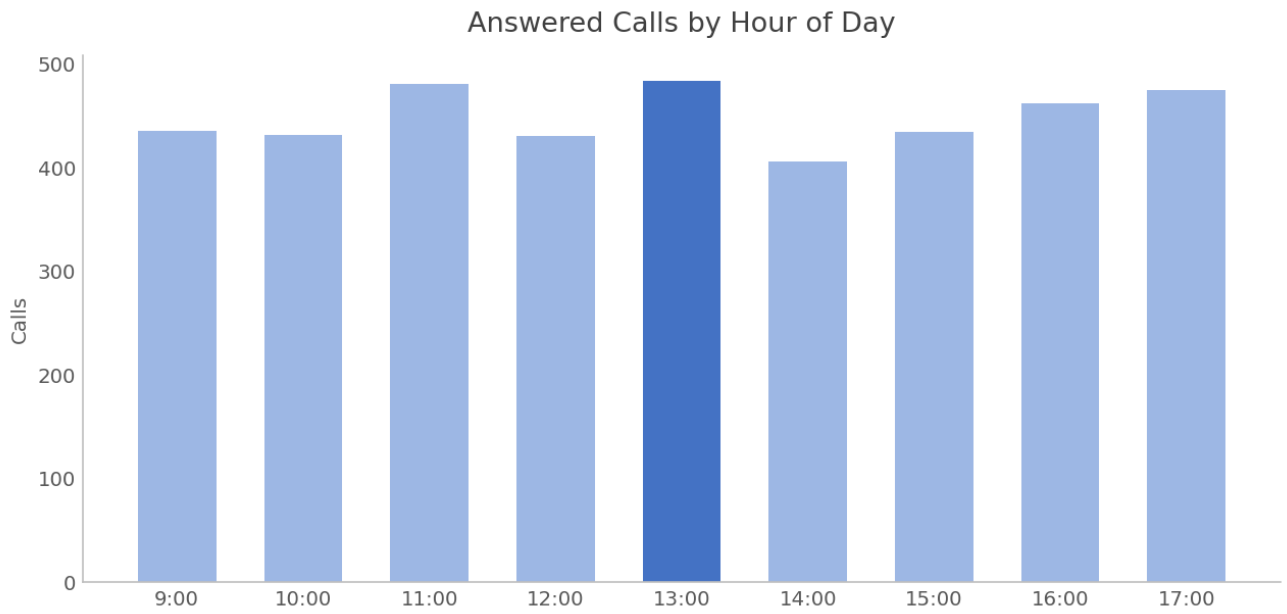

- What share of calls go unanswered, and when do they happen?
- How do agents compare on resolution rate, speed of answer and satisfaction?
- What drives customer satisfaction: speed of answer, or something else?
- Which call topics are hardest to resolve?

The data

Each row is one call: agent, date, time, topic, whether it was answered, whether it was resolved, speed of answer, talk duration and a 1 to 5 satisfaction rating. 946 of the 5,000 calls, 18.9%, were never answered, so have no speed, duration or satisfaction recorded. Two calculated fields in the workbook convert the stored talk-duration time into seconds and extract the hour of each call from its timestamp, so both could be aggregated and charted.

Calls cluster around the middle of the day

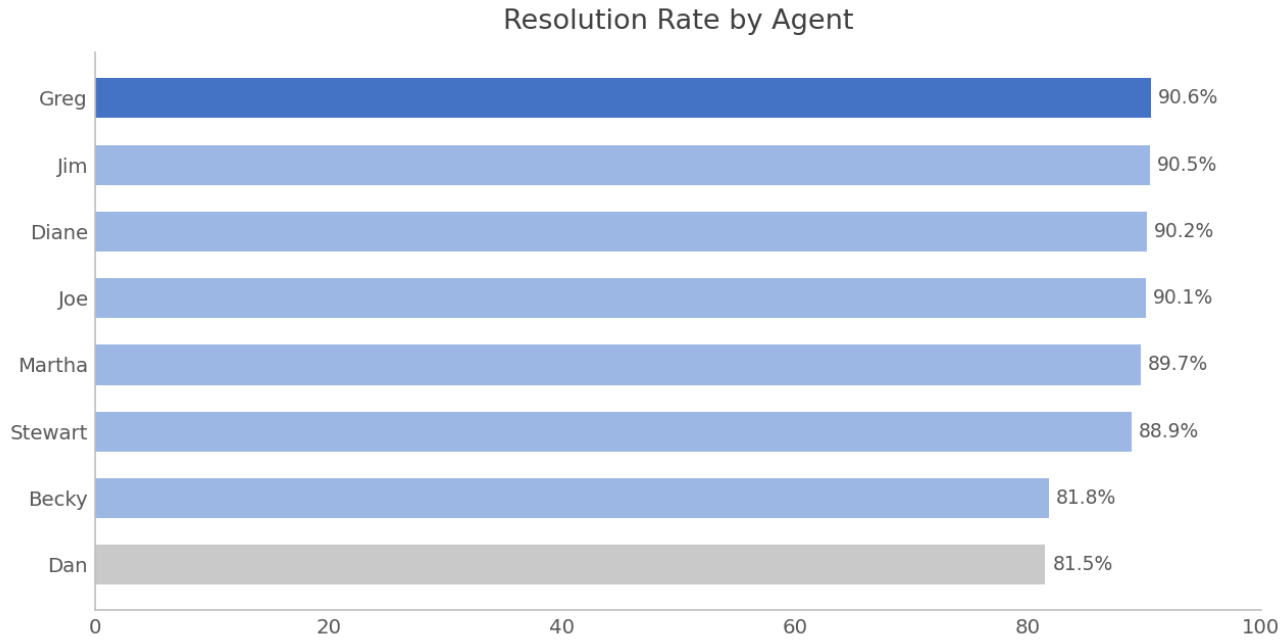

Volume is fairly even through the day, with a mild peak around 11am and 1 to 2pm. There is no single overwhelmed hour. The unanswered rate tells a similar story: it holds in an 18 to 20% range every weekday, Wednesday and Friday slightly higher than the rest, so missed calls look like a constant staffing gap rather than a specific rush period.

Answered calls by hour of day.

Two agents resolve noticeably fewer calls

Six of the eight agents resolve 89 to 91% of the calls they answer. Becky and Dan sit apart from the group at 81.8% and 81.5%, a gap of roughly 8 to 9 points. Their average speed of answer and satisfaction scores are in line with everyone else, so the gap is specific to resolution rather than a general performance difference.

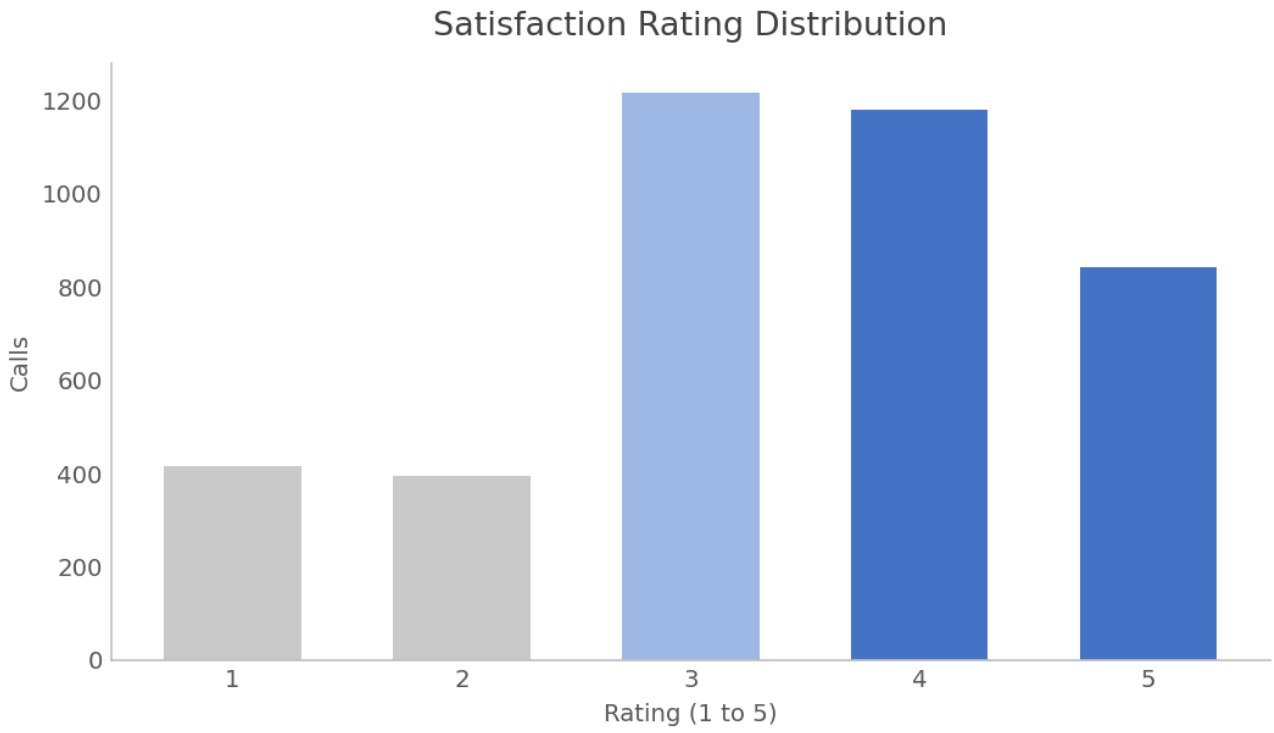

Resolution rate by agent, calls that were answered.

Speed of answer does not predict satisfaction

This is worth stating plainly because it argues against an intuitive assumption. The correlation between speed of answer and satisfaction rating across all 4,054 answered calls is 0.001, effectively zero. Satisfaction instead splits cleanly into two groups: the large majority of calls score 3 or above, and a smaller block scores 1 to 2, with very little in between. That pattern looks more like whether the issue got resolved than how long

someone waited.

Distribution of satisfaction ratings across all answered calls.

Topic differences are small

Resolution rate by topic ranges narrowly, from 86.2% on Streaming to 89.4% on Admin Support, a 3.2 point spread. Nothing here stands out as a specific problem topic the way the two agents do.

Interpretation and limitations

The clearest lever is agent-level, not topic or timing: closing the resolution gap for Becky and Dan alone would lift roughly 1,040 calls a quarter from an 82% resolution rate toward the 90% the rest of the team already hits. Since satisfaction tracks resolution rather than wait time, that is also the change most likely to move customer satisfaction. Adding staff to shorten hold times, by contrast, is not supported by this data.

The dataset is one quarter from a single center, so it cannot say whether the agent gap is a training issue, a difference in the calls they happen to get, or something else. It also has no information about why unresolved calls failed, which would be the natural next thing to add.

What is in the workbook

Sheet	Contents
Call Volume During Day / During Week	Volume patterns by hour and weekday
Calls Per Day	Daily call counts over the quarter
Resolution Rate / by Agent	Overall and agent-level resolution
Resolved Calls by Agent	Resolved call counts per agent

Sheet	Contents
Satisfaction Rating	Distribution of ratings
Speed of Answer by Agent	Average wait time per agent

Portfolio project built on a public call center dataset.
